NTI Upstream 2013 Webinar Series

Drug Use in Pregnancy: Focus on the Newborn

Webinar #4: Breastfeeding Guidelines for Chemically Dependent Women

Women with a chemical dependence frequently have poor family and social support networks and few positive relationships with other women. These factors contribute to low rates of breastfeeding in women addicted to illicit drugs. However, breastfeeding can enhance the mother/child relationship and is the healthiest means of feeding the infant. This session will discuss the pros and cons of breastfeeding by women with a history of substance abuse and will provide guidelines that encourage breastfeeding but at the same time protect the newborn from harm by substances that cross into the breast milk.

About the NTI Upstream 2013 Webinar Series

Newborns prenatally exposed to maternal substances of abuse make up an ever-growing portion of the United States' population of children. The most recent data from the National Institute on Drug Abuse suggest that over 1 million children per year are exposed to alcohol and illicit substances during gestation. The health consequences for these newborns are enormous, and the implications for early management are quite complicated. This webinar series will explore the medical and neurobehavioral outcomes of newborns exposed prenatally to illicit drugs and the legal and child welfare implications for the children and their families.
